A HYBRID FREQUENCY-TIME DOMAIN EQUALIZER

ABSTRACT OF THE DISCLOSURE

100 mark to the transmission to the transmission of the transmissi

5

A channel decoder employs a hybrid frequency-time domain equalizer for effectively combining a frequency domain equalizer with a time domain equalizer to achieve superior static and dynamic multi-path performance compared to conventional decision feedback equalizers. A frequency domain equalizer structure is included within the forward path of a time domain, decision feedback equalizer, with both the frequency domain and time domain portions employing a common error vector. Updates to the taps (frequency bins) may be adapted individually, or fully within the frequency domain without altering the feedback Improved performance, including performance for noisy channels with deep notches, is achieved, and the frequency domain equalizer portion is relieved equalizing minimum phase zeros of the channel.
